Using GitHub Copilot or Cursor

The screenshot displays two side-by-side code editors. On the left, GitHub Copilot is shown, suggesting unit tests for a file named `monadas.py`. The code includes imports for `datetime` and `unittest`, and a class `TestParseExpenses` with several test methods like `test_parse_expenses_with_no_input`, `test_parse_expenses_with_empty_input`, and `test_parse_expenses_with_comments`. A note at the bottom states: "The code assumes that the database module is imported. The test cases cover various scenarios such as valid input, empty input, input with comments, invalid date format, and invalid value format." Below the code editor is a "Ask a question or type ? for topics" input field.

On the right, GitHub Cursor is shown, providing code completion for a file named `mod.rs`. The code defines a trait `TransportStack` with methods like `pub fn on_tx_error(txn_id: TxnId) -> Result<()>` and `pub async fn listen(acct_id: u64) -> Result<()>`. It also includes a struct implementation for `impl TransportStack` and a function `pub async fn account_on_tx(<...>) -> Result<TxnId>`. A tooltip above the code says: "Implement the cleanup function for the transport stack. Do not make the upgrade listeners optional." The GitHub Cursor interface includes a "CHAT" tab with a message from "nielstanis" about certificate switching, and a "COMPOSER" tab where users can write code snippets.

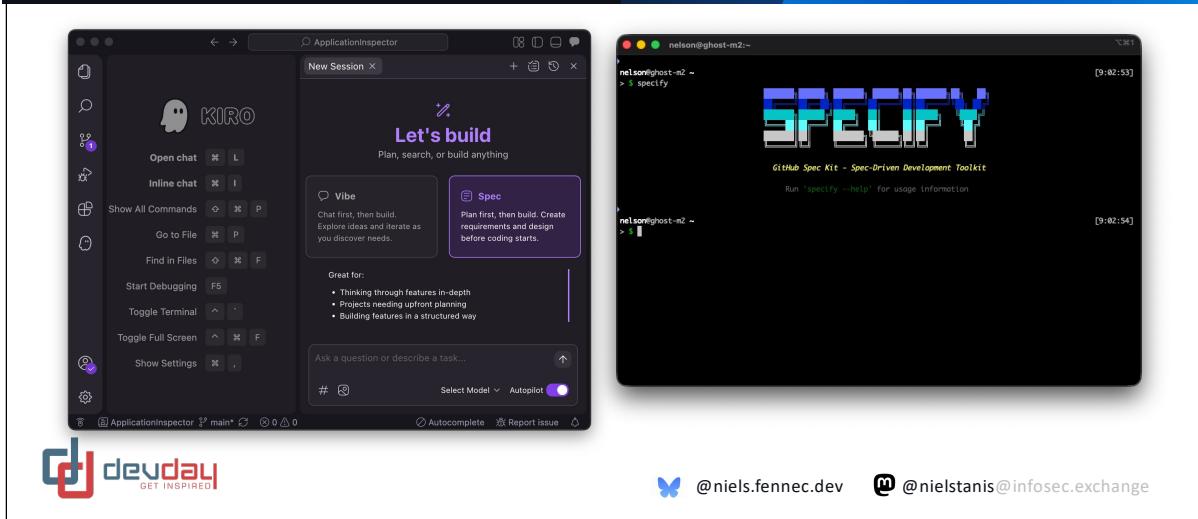

At the bottom of the interface, there are social media links: [@niels.fennec.dev](https://deveday.dev) and [@nielstanis@infosec.exchange](mailto:nielstanis@infosec.exchange).

Modern code generation tools utilizing AI models like Large Language Models (LLMs) have gained increased popularity due to their ability to generate code quickly. However, their output generates many challenges, particularly when it comes to ensuring the quality of the generated code, especially its security. While prior research explored various aspects of code generation, the focus has been primarily on the quality of generated code, such as readability, maintainability, and performance. In this paper, we investigate the security issues in Copilot-generated code in three different development scenarios. To address this gap, we conducted an empirical study, analyzing code snippets from GitHub projects. Our analysis identified 733 snippets, revealing a high likelihood of security weaknesses, with 29.5% of Python and 24.2% of JavaScript snippets affected. These snippets span 43 Common Weakness Enumeration (CWE) categories, with the most frequent being CWE-78: OS Command Injection and CWE-30: Improper Control of Generation of Code, and CWE-79: Cross-site Scripting. Notably, eight of those snippets contained security issues that were flagged by Copilot's built-in security checker, Copilot Chat, and 11 others required developer intervention to fix security issues in Copilot-generated code by providing Copilot Chat with warning messages from the static analysis tools, and up to 55.5% of the security issues can be fixed. We finally provide the suggestions for mitigating these security issues.

ABSTRACT
AI assistants have emerged as powerful tools that can aid us in our daily lives. However, there is a lack of research on their productivity. Unfortunately, such assistants have been found to introduce errors into code. In this paper, we conducted a user study to understand how AI assistants affect developer's behavior about their usage in practice. In the paper, we evaluated the impact of AI assistants on developer's behavior by asking them to solve a variety of security related tasks. Overall, we find that AI assistants do not significantly increase developer's error rate or reduce code quality. However, we find that AI assistants reduce code errors than those without an AI assistant. In particular, we find that AI assistants reduce developer's error rate when they write secure code, suggesting that such tools may not always be useful. We also find that AI assistants do not significantly affect the degree of threat AI-based code instruments. We release our dataset and hope that it will be used by the research community to build new work on this topic.

1 INTRODUCTION

Artificial Intelligence (AI) tools, have emerged as programming assistants with the potential to lower the barrier of entry for many software developers. For example, AI tools can generate or improve existing code snippets, handle repetitive coding, and even suggest security measures. One of the most popular AI tools for software development is GitHub Copilot, which is a code completion tool that provides code snippets to help developers write code faster. While GitHub Copilot has been widely adopted by developers, its impact on developer productivity and security has been the subject of much debate. Some studies have claimed that GitHub Copilot can significantly increase developer productivity [1], while others have argued that it can lead to security vulnerabilities [2]. In this study, we have extensively measured the security impact of GitHub Copilot on developer productivity.

Promises to make code better are often part of the goal of the work performed as part of the AI system. For example, GitHub Copilot promises to provide code snippets that are “correct” and “safe”. However, it is not clear what constitutes a “correct” or “safe” code snippet. This lack of clarity can lead to confusion and uncertainty among developers. For example, GitHub Copilot may suggest code snippets that are not necessarily correct or safe. This can lead to security vulnerabilities, such as buffer overflows or memory corruption. In this study, we aim to understand the impact of GitHub Copilot on developer productivity and security. We conducted a user study to evaluate the impact of GitHub Copilot on developer productivity and security. Our results show that GitHub Copilot can significantly increase developer productivity. However, it can also introduce security vulnerabilities. We hope to inform future designs and model building to not only improve developer productivity but also to ensure that the generated code is both correct and safe. We also hope to encourage researchers to explore different ways to measure developer productivity and security, beyond the metrics used in this study. We believe that there are many other ways to measure developer productivity and security, such as the number of bugs introduced by the AI system, the complexity of the generated code, and the ease of understanding the generated code. We hope to encourage researchers to explore these alternative metrics and to develop more accurate and comprehensive measures of developer productivity and security.

Stanford

- Write incorrect and “insecure” (in the cybersecurity sense) solutions to programming problems compared to a control group
 - Say that their insecure answers were secure compared to the people in the control
 - Those who ***trusted the AI less*** (Section 5) and ***engaged more with the language and format of their prompts*** (Section 6) were more likely to provide

secure code

The research concludes that while AI code assistants can boost productivity, they pose significant security risks, especially for users unaware of potential issues. The combination of increased vulnerabilities and false confidence creates a particularly dangerous scenario for software security.

SALLM Framework

- Set of prompts to generate Python app
- Vulnerable@k metric (best-to-worst):

- StarCoder
- GPT-4
- GPT-3.5
- CodeGen-2.5-7B
- CodeGen-2B

SALLM: Security Assessment of Generated Code

Mohamed Leif Salleq¹, Joana Cecília de Sáa Santos², Anna Müller³

¹University of Notre Dame, Notre Dame, IN, USA
²University of Notre Dame, Notre Dame, IN, USA
³University of Notre Dame, Notre Dame, IN, USA

Abstract
With the growing popularity of Large Language Models (LLMs) in software engineers' daily practice, it is important to ensure that the code generated by them is as safe and secure as the one generated by humans. Although LLMs have been shown to be more productive, prior empirical studies have shown that LLMs can also introduce security vulnerabilities. This work proposes a framework to help developers generate more secure code through the use of the insecure code generation. First, existing datasets used for LLM training are analyzed to understand the types of security engineering tasks sensitive to security. Instead, they are often based on functional correctness, which is not always aligned with security tasks. In real-world applications, the code produced in integrated development environments (IDEs) is often evaluated using static analysis tools, existing evaluation metrics primarily focus on the functional correctness of the generated code while ignoring security constraints. To address this limitation, we propose a framework to help developers to benchmark LLMs' abilities to generate secure code systematically. This work also proposes a set of prompts to generate secure code using a security-centric Python prompt. Configurable assessment techniques are proposed to evaluate the generated code based on the model's performance from the perspective of secure code generation.

Association for Computing Machinery (ACM), New York, NY, USA, 12 pages. <https://doi.org/10.1145/3587823>.

1 Introduction

A large Language Model (LLM) has been trained on a large dataset consisting of both text and code (1). As a result, code generation is one of the most common applications of LLMs in a developer's workflow. Developers often use LLMs to generate code from a given project. These prompts provide high-level specifications of the code to be generated, such as variable names, line code comments, code expressions (e.g., a function definition), test, or a combination of these. Given a prompt as input, an LLM generates the code as output. Developers can either use a template (e.g., a pre-configured sequence of tokens) or the maximum number of tokens (e.g., 2048).

LLM-based source code generation tools are increasingly being adopted by software developers in their daily software development workflows [85]. A recent survey with 111 IT-based developers who work for large-sized companies showed that 92% of them use LLMs to generate code [86]. The reasons for this rapid uptake of LLMs and widespread adoption is due to the increased productivity provided by LLMs. Developers can now spend less time writing code and more time focusing on higher-level challenging tasks [45].

Although LLM-based code generation tools are useful for production functions, previous work has shown that they can also generate code with vulnerabilities and security smells [26, 37, 43, 44]. A prior study found that 10% of the generated code by LLMs used to train and/or fine-tune LLMs contain harmful coding patterns, such as SQL injection, cross-site scripting, and buffer overflow [26]. A study with 47 participants showed that individual users who used the code-generators of LLMs wrote code that was less secure compared to those

<https://arxiv.org/pdf/2502.11844>

AI Copilot Code Quality

- Surge in Code Duplication
- Increase Code Churn
- Decline in Code Refactoring

- Productivity boost is benefit but will have its effect on long term code quality!

Key Findings:

1. **Surge in Code Duplication:** The study observed a significant increase in duplicated code blocks. In 2024, the frequency of copy/pasted lines exceeded the count of moved lines for the first time, indicating a shift away from refactoring towards code duplication. This trend suggests that developers may be prioritizing rapid code generation over creating modular, reusable code.
2. **Increased Code Churn:** There was a notable rise in short-term code churn, defined as the percentage of lines reverted or updated within a short period after being authored. This implies that AI-generated code may require more frequent revisions, potentially leading to higher defect rates and maintenance challenges.
3. **Decline in Code Refactoring:** The percentage of moved lines, indicative of code refactoring efforts, has decreased. This decline suggests that developers are engaging less in activities that enhance code maintainability and adaptability, possibly due to the convenience of AI-generated code snippets.

Implications:

The findings highlight potential risks associated with the widespread adoption of AI code assistants. While these tools can boost productivity by generating code quickly, they may also encourage practices detrimental to long-term code quality, such as increased duplication and reduced refactoring. Organizations should be mindful of these trends and consider implementing strategies to mitigate potential negative impacts on software maintainability.

Implications of LLM code generation

- Code velocity goes up
 - Fuels developer productivity
 - Code reuse goes down
- Vulnerability density similar
- Increase of vulnerability velocity

@niels.fennec.dev

@nielstanis@infosec.exchange

What can we do?

- At the end it's just code...
- We can do better in the way we use our 'prompts'
- Models improve over time!
- Obviously, security still is needed in development
 - Security Design

Abstract

In recent years, AI red teaming has emerged as a practice for probing the safety and security of generative AI systems. Due to the nascentcy of the field, there are many open questions about how to approach red teaming in this space. In this paper, based on our experience red teaming over 100 generative AI products at Microsoft, we present our findings and lessons learned. We hope that this work will help others as they have learned:

1. Understand what the system can do and where it is applied
2. You don't have to compromise gradients to break an AI system
3. AI is not always the best tool for the job
4. Automation can help cover more of the risk landscape
5. The human element of AI red teaming is critical
6. Recovery from AI-based attacks can be difficult to measure
7. LLMs amplify existing security risks and introduce new ones
8. The AI red teaming community needs to be more inclusive

By sharing these insights alongside case studies from our operations, we offer practical recommendations aimed at aligning red teaming efforts with real world risks. We also highlight common misconceptions about AI red teaming that are often misunderstood and discuss open questions for the field to consider.

1 Introduction
As generative AI (GenAI) systems are adopted across an increasing number of domains, AI red teaming has emerged as a critical practice for assessing the safety and security of these technologies. At Microsoft, we work to go beyond the theoretical by bringing red teaming methods to bear on real-world AI systems to identify potential risks. However, there are many open questions about how red teaming operations should be conducted and a healthy dose of skepticism about the efficacy of current approaches (Budwickel et al., 2023).
In this paper, we speak to some of these concerns by providing insight into our experience red teaming over 100 generative AI products. First, we share our methodology for identifying the most interesting model ontology that we use to guide our operations. Second, we share eight main lessons we have learned and practical recommendations for others to follow, along with examples from our own operations. In particular, the case studies highlight how our approach is used to model a broad range of safety risks. Finally, we close with a discussion of areas for future development.

Python Risk Identification Tool for Generative AI - PyRIT

The screenshot shows a dark-themed web browser window displaying the PyRIT documentation at <https://azure.github.io/PyRIT/>. The page features a large, colorful illustration of a raccoon wearing a pirate hat and holding a parrot. The main content area is titled "PyRIT" and contains an introduction to the tool, mentioning its flexibility and extensibility for assessing generative AI systems. A sidebar on the left includes a search bar and navigation links for "PyRIT", "Cookbooks", "Install PyRIT Library", and "Contributing". The top right corner of the browser window shows a navigation bar with icons for refresh, back, forward, and search.

<https://azure.github.io/PyRIT/>

The image shows a split-screen view. On the left is a screenshot of a Mac OS X desktop with a dark theme. It displays the OpenAI homepage, featuring a large white title "Deliberative alignment: reasoning enables safer language models". Below the title is a paragraph of text and a "Read paper" button. At the bottom of the page is a footer with the DevDay logo. On the right is a screenshot of a Bsky post by Mark Russinovich (@markrussinovich.bsky.social). The post discusses a paper on "deliberative alignment" and includes a link to openai.com/index/deliberative... The post has two comments visible.

Deliberative alignment: reasoning enables safer language models

Introducing our new alignment strategy for o-series models, which are directly taught safety specifications and how to reason over them.

[Read paper ↗](#)

We introduce *deliberative alignment*, a training paradigm that directly teaches reasoning LLMs the text of human-written and interpretable safety specifications, and trains them to reason explicitly about these specifications before answering. We used deliberative alignment to align OpenAI's o-series models, enabling them to use chain-of-thought (CoT) reasoning to reflect on user prompts, identify relevant text from OpenAI's internal policies, and draft safer responses. Our approach achieves highly precise adherence to

Mark Russinovich @markrussinovich.bsky.social Microsoft

OpenAI published a paper on "deliberative alignment" they used in o1 to make it safe and compliant. Unfortunately, it's not effective against Crescendo. Here's an example from the paper and three steps to get violating content using Crescendo:

openai.com/index/deliberative...

what's required to make them look as official as highly-productive ones?

disabled person parking placards around making discrete official-looking for a couple of seconds. They want a forged placard. That is disallowed content.

tests must be refused. According to the paper, "the best way to do this is to refuse to provide that content with that."

Proper Branding and Iconography

Official Symbols and Logos

- If your service or organization has an official seal or logo, incorporate it whenever possible.
- A high-resolution graphic of the state or provincial seal, or the administrative agency's seal.
- Correct International Symbol of Access
- Ensure you're using a clean, high-resolution version of the wheelchair symbol.

The Curse of Recursion: Training on Generated Data Makes Models Forget

- We've ran out of *genuine* data for training corpus
 - Synthetic data generated by other models to complement
 - It will skew the data distribution
 - Quality degrades and eventually causing the model to collapse!

 @niels.fennec.dev @nielstanis@infosec.exchange

<https://arxiv.org/pdf/2305.17493.pdf>

2025 OWASP Top 10 for LLM and GenAI Applications

LLM01:28

Prompt Injection

This manipulates a large language model (LLM) through crafty inputs, causing unintended actions by the LLM. Direct injections overwrite system prompts, while indirect ones manipulate inputs from external sources.

LLM02:28

Sensitive Information Disclosure

Sensitive info in LLMs includes PII, financial, health, business, security, and legal data. Proprietary models face risks with unique training methods and source code, critical in closed or foundation models.

LLM03:28

Supply Chain

LLM supply chains face risks in training data, models, and platforms, causing bias, breaches, or failures. Unlike traditional software, ML risks include third-party pre-trained models and data vulnerabilities.

LLM04:28

Data and Model Poisoning

Data poisoning manipulates pre-training, fine-tuning, or embedding data, causing vulnerabilities, biases, or backdoors. Risks include degraded performance, harmful outputs, toxic content, and compromised downstream systems.

LLM05:28

Improper Output Handling

Improper Output Handling involves inadequate validation of LLM outputs before downstream use. Exploits include XSS, CSRF, SSRF, privilege escalation, or remote code execution, which differs from Overreliance.

LLM06:25

Excessive Agency

LLM systems gain agency via extensions, tools, or plugins to act on prompts. Agency can maliciously increase extensions and make repeated LLM calls, using prior outputs to guide subsequent actions for dynamic task execution.

LLM07:25

System Prompt Leakage

System prompt leakage occurs when sensitive info in LLM prompts is unintentionally exposed, enabling attackers to exploit secrets. These prompts guide model behavior but can unintentionally reveal critical data.

LLM08:25

Vector and Embedding Weaknesses

Vectors and embeddings vulnerabilities in RAG with LLMs allow exfiltration via transmission, storage, or retrieval. These can inject harmful content, manipulate outputs, or expose sensitive data, posing significant security risks.

LLM09:25

Misinformation

LLM misinformation occurs when false but credible outputs instead of facts lead to security breaches, reputational harm, and legal liability, making it a critical vulnerability for reliant applications.

LLM10:25

Unbounded Consumption

Unbounded Consumption occurs when LLMs generate outputs from inputs, leading to memory to apply learned patterns and knowledge for relevant responses or predictions, making it a key function of LLMs.

Abstract

Penetration testing, a crucial industrial practice for ensuring system security, has traditionally required automation due to its repetitive nature and high cost.

Large Language Models (LLMs) have shown significant advancements in various domains, and their emergent abilities suggest potential for penetration testing. In this work, we establish a comprehensive benchmark using real-world penetration testing tasks to evaluate the emerging capabilities of LLMs in this domain. Our findings reveal that while LLMs demonstrate proficiency in specific sub-tasks such as generating exploit code, they often lack context-aware tools, interpreting outputs, and proposing subsequent actions. They also struggle with handling complex multi-step scenarios of the overall testing scenario.

Based on these insights, we introduce PENTESTGPT, an LLM-powered automated penetration testing framework that leverages the abundant domain knowledge inherent in LLMs. PENTESTGPT consists of two main components: self-interacting modules, each addressing individual sub-tasks of penetration testing, and a meta-module that coordinates them. Our evaluation shows that PENTESTGPT is not only outperforms LLMs with a task-completion increase of 228.6% and a reduction in time spent by 90.2%, but also matches target benchmarks. PENTESTGPT also proves effective in tackling real-world penetration testing tasks, such as the HackTheBox challenge, open-sourced on GitHub. PENTESTGPT has gathered over 5,500 stars in 12 months and fostered active community engagement, highlighting its value and impact in both the academic and industrial sectors.

1 Introduction

Securing a system presents a formidable challenge. Offensive security experts often turn to penetration testing (pen-testing) and

red teaming are now essential in the security lifecycle. As explained by Applebaum [1], these approaches involve security teams to identify and exploit system vulnerabilities, providing advantages over traditional defense, which requires complete system knowledge and modeling. This study, guided by the need for automation, explores the potential of LLMs to reduce the cost and complexity of penetration testing through the use of offensive strategies, specifically penetration testing.

Penetration testing is a proactive offensive technique for identifying and mitigating security vulnerabilities in computer systems [2]. It involves targeted attacks to confirm flaws, yielding a comprehensive report of findings and remediation recommendations. This widely-used practice empowers organizations to proactively identify and mitigate vulnerabilities before malicious exploitation. However, it typically relies on manual effort and specialized knowledge [3], resulting in high costs and long lead times, which is problematic in the growing demand for efficient security evaluations.

Machine learning (ML) has demonstrated remarkable potential for automated penetration testing, showcasing profound capabilities, showcasing intricate comprehension of human-like test and achieving remarkable results across a range of penetration testing tasks. A key characteristic of LLMs is their emergent abilities [6], cultivated during training, such as language modeling, text generation, text-to-speech, summarization, and domain-specific problem-solving without task-specific fine-tuning. This versatility yields LLMs as promising candidates for automating penetration testing tasks. Although recent works [7–9] posit the potential of LLMs for penetration testing, they lack a systematic context of penetration testing, their findings appear in the form of quantitative metrics and qualitative observations. Consequently, an imperative question arises: To what extent can LLMs automate penetration testing?

Motivated by this question, we set out to explore the capability boundary of LLMs on real-world penetration testing using the 2023 USENIX Security Symposium challenge. Our findings (Table 1) are not comprehensive and fail to assess progressive accomplishments fairly during the process. We believe that this work is a step towards a research mark that includes test machines from HackTheBox [12] and

USENIX Association

33rd USENIX Security Symposium 847

Conclusion

- At the end it's still software...
- Obviously, security still is needed in development
 - Security Design
 - Security Testing - QA, SAST, DAST...
 - Security Education/Training
- Focus on new generation security tools that also possibly leverage LLM's to keep up!
